

The Technical Architecture of Real-Time Aviation Surveillance: A Comprehensive Guide to ADS-B and the Flightradar24 Ecosystem

Published: September 4, 2025 | Index ID: #753

In the contemporary aviation landscape, the ability to track aircraft in real-time has transitioned from an exclusive military and Air Traffic Control (ATC) capability to a democratized digital service accessible to anyone with an internet connection. At the forefront of this revolution is **Flightradar24**, a global flight tracking service that provides real-time information about thousands of aircraft around the world. This article provides an exhaustive technical analysis of the systems that power this infrastructure, focusing on **Automatic Dependent Surveillance-Broadcast (ADS-B)**, the hardware components involved in signal reception, and the complex data processing pipelines required to visualize global air traffic.

1. Theoretical Framework of Modern Flight Tracking

To understand how platforms like Flightradar24 operate, one must first grasp the shift from traditional Primary Surveillance Radar (PSR) to modern digital surveillance methods. Traditional radar relies on the reflection of radio waves off an aircraft's fuselage. In contrast, modern flight tracking is predominantly based on cooperative surveillance technologies.

Automatic Dependent Surveillance-Broadcast (ADS-B)

ADS-B is the cornerstone of modern aviation surveillance. The acronym defines its core operational principles:

- **Automatic:** It requires no pilot or external input to transmit information.
- **Dependent:** It depends on data from the aircraft's navigation system (typically GPS).
- **Surveillance:** It provides position, altitude, velocity, and identification data.
- **Broadcast:** It continuously transmits this data to any receiver within range.

The system operates on a frequency of **1090 MHz** (for the 1090 Extended Squitter) or 978 MHz (in the United States for Universal Access Transceivers). The data packet transmitted by the aircraft includes its ICAO 24-bit address, squawk code, latitude, longitude, barometric altitude, and heading.

Multilateration (MLAT)

For aircraft not yet equipped with ADS-B transponders—specifically older airframes or those using older Mode S transponders—Flightradar24 utilizes **Multilateration (MLAT)**. This process calculates the position of an aircraft by measuring the **Time Difference of Arrival (TDOA)** of a signal at four or more separate ground-based receivers. By knowing the precise location of the receivers and the exact time the signal was received (synchronized via GPS clocks), the system can solve complex geometric equations to pinpoint the aircraft's 3D coordinates.

2. Technical Analysis of ADS-B Hardware and Receivers

The ground-based segment of the Flightradar24 network consists of tens of thousands of receivers. A significant portion of this network is comprised of community-hosted hardware, often identified by technical SKUs such as **B01N6B68A4** (a common identifier for high-performance SDR kits used in flight tracking). These devices are typically based on **Software Defined Radio (SDR)** technology.

Core Components of a Tracking Station

1. Antenna: Optimized for the 1090 MHz frequency. High-gain vertical colinear antennas are preferred to maximize the line-of-sight range, which can exceed 250 nautical miles under ideal conditions.
2. Filter and Low-Noise Amplifier (LNA): Given that the 1090 MHz band is crowded, a high-pass or band-pass filter is essential to reduce interference from GSM and LTE signals. An LNA boosts weak signals from distant aircraft before they reach the receiver.
3. SDR Dongle: Devices like the RTL2832U-based tuners (often referenced by the ASIN B01N6B68A4 in logistics) convert the analog radio frequency into digital IQ samples.
4. Processor: Usually a low-power single-board computer (SBC) like a Raspberry Pi, which runs decoders such as dump1090 to translate binary Mode S frames into readable JSON or CSV data.

Comparison of Surveillance Technologies

Feature	Primary Radar (PSR)	Secondary Radar (SSR)	ADS-B
Signal Source	Reflected Pulse	Transponder Reply	Active Broadcast
Accuracy	Low (Range-dependent)	Medium	High (GPS-based)
Update Rate	5-12 seconds	4-10 seconds	1-2 seconds
Cost of Ground Station	Very High	High	Low
Information Richness	Position only	ID, Altitude	ID, Position, Velocity, Intent

3. Data Processing and Algorithmic Integration

Once a receiver decodes a packet, the data is sent to Flightradar24’s central servers. This involves a massive-scale ingestion architecture capable of handling millions of updates per second. The data pipeline involves several critical stages:

The Ingestion Layer

Raw JSON data from diverse geographical locations is uploaded via encrypted TCP streams. The server must first perform **de-duplication**. Since multiple receivers often see the same aircraft, the system must determine which data point is the most accurate based on signal strength (RSSI) and timestamp precision.

Geometric Validation

The system applies **sanity checks** to the incoming data. If an aircraft’s reported position implies a supersonic speed (for a Cessna) or a sudden jump of 500 miles, the data point is flagged as an anomaly or spoofed signal and discarded. This prevents "ghost aircraft" from appearing on the map due to multipath interference or malfunctioning hardware.

Data Merging (Sensor Fusion)

Flightradar24 doesn't rely solely on ADS-B. It integrates data from:

- FAA SWIM (System Wide Information Management): Provides radar data for North American airspace (often with a 5-minute delay for security).
- FLARM: A low-power system used by gliders and light aircraft.
- Satellite-based ADS-B: Utilizing constellations like Iridium NEXT to track aircraft over oceans where ground-based receivers cannot reach.

4. Regional Case Study: Indonesia's Aviation Infrastructure

Indonesia presents a unique challenge for flight tracking due to its archipelagic geography and mountainous terrain. Key hubs like **Yogyakarta Adisucipto International Airport (JOG/WAHH)** require dense receiver networks to overcome signal shading caused by volcanic topography.

Operational Challenges in the Indonesian Context

The tropical environment of Indonesia leads to high humidity and frequent thunderstorms, which can cause signal attenuation. Furthermore, the expansion of the New Yogyakarta International Airport (YIA) has shifted traffic patterns, requiring Flightradar24 to recalibrate its MLAT clusters in the region. The high density of traffic in the

Jakarta-Singapore corridor makes this one of the most data-intensive regions in the world for ADS-B monitoring.

Airport Code	Airport Name	Primary Coverage Type	Receiver Density
CGK/WIII	Soekarno-Hatta Intl	ADS-B / MLAT / Radar	High
DPS/WADD	Ngurah Rai Intl	ADS-B / Satellite	Medium-High
JOG/WAHH	Adisucipto Intl	ADS-B / MLAT	Medium
SUB/WARR	Juanda Intl	ADS-B / MLAT	High

5. Implementation Guide: Deploying a Professional ADS-B Station

For organizations or technical enthusiasts looking to contribute to the global network and access professional-grade data, following a standardized deployment procedure is vital.

Step-by-Step Installation Workflow

- Site Survey:** Identify a location with a 360-degree unobstructed view of the horizon. Obstructions like tall buildings or trees significantly reduce the maximum range.
- Hardware Assembly:** Connect the 1090 MHz antenna to a high-quality coaxial cable (e.g., LMR-400) to minimize signal loss. Connect the cable to the SDR dongle (B01N6B68A4 or similar).
- Software Configuration:** Install a Linux-based OS on the SBC. Use the following command structure to install the tracking client: `sudo bash -c "$(wget -O - https://repo-feed.flightradar24.com/install_fr24_rpi.sh)"`.
- Calibration:** Adjust the Gain Settings. Setting the gain too high can saturate the receiver with noise, while setting it too low will result in missed detections of distant aircraft.
- Data Verification:** Access the local web interface (usually port 8754) to monitor the number of aircraft tracked and the signal-to-noise ratio.

6. Troubleshooting and Operational Optimization

Maintaining a 24/7 flight tracking station involves addressing several common technical failure modes.

Common Issues and Solutions

- Signal Interference:** If the station is near a cellular tower, the 1090 MHz signal may be drowned out. Solution: Install a specialized SAW (Surface Acoustic Wave) filter between the antenna and the SDR.
- Power Supply Instability:** Raspberry Pi devices are sensitive to voltage drops. Solution: Use a dedicated 5V/3A power supply and avoid powering the SDR through unpowered USB hubs.
- Thermal Throttling:** Decoding ADS-B data is CPU-intensive. In warm climates like Indonesia, the SDR and CPU can overheat. Solution: Use passive heat sinks and active cooling fans within the enclosure.

7. Future Trajectory of Flight Tracking Technology

The future of aviation surveillance is moving toward **Space-Based ADS-B**. By placing ADS-B receivers on Low Earth Orbit (LEO) satellites, platforms like Flightradar24 can eliminate "black holes" in coverage over the Pacific and Atlantic oceans. This provides a continuous, global 1-second update interval for every aircraft on the planet, significantly enhancing search and rescue capabilities and fuel efficiency through more precise oceanic routing.

Furthermore, the integration of **Artificial Intelligence (AI)** and **Machine Learning (ML)** is beginning to play a role in predictive analytics. By analyzing historical flight paths and real-time weather data, these systems can predict Estimated Time of Arrivals (ETAs) with unprecedented accuracy, even in the face of significant holding patterns or

diversions. The technical synergy between ground-based hardware, satellite constellations, and advanced data processing ensures that the aviation industry remains more transparent and safer than ever before.

As we continue to refine these systems, the role of the technical community in maintaining the ground-based receiver network remains indispensable. Whether through professional installations at airports like Yogyakarta or hobbyist setups in residential areas, every node in the network contributes to a more comprehensive and accurate picture of our global skies.
